Preface

Just how important is irrigated agriculture to the Nebraska economy? This question was first addressed nearly forty years ago in a study conducted by Drs. Theodore W. Roesler and F. Charles Lamphear, University of Nebraska Department of Economics. This initial study was updated in 1972 and, again, in 1991.

The latest update study for 2003 was recently completed by Dr. Charles Lamphear, emeritus professor, University of Nebraska-Lincoln (UN-L). He was assisted by emeritus professors Dr. Roy Frederick, UN-L Department of Agriculture Economics and Dr. Dale Flowerday, UN-L Department of Agronomy and Horticulture, along with several UN-L extension specialists.

The results of the 2003 study are summarized in this report. As principal investigator, Dr. Charles Lamphear takes full responsibility for the study's methodology, data, and findings.

Current Economic Impact of Irrigated Crop Production

Introduction

The 2003 irrigation study provides an accounting of the total impact that irrigated agriculture has on the Nebraska economy. Economic impact estimates were calculated for two scenarios. The first scenario assumed normal precipitation prior and during the 2003 crop growing season. The second scenario considered the drought conditions that actually occurred prior and during the 2003 growing season. The purpose for the two scenarios was to give a full accounting of irrigated agriculture's importance to the state's economy.

For both scenarios, total economic impact was defined to include three economic effects: direct effect, indirect effect, and consumption effect. Direct economic effect was defined as the 2003 value of crop output. Indirect economic effect was defined as the business-to-business purchases/sales generated by crop production activity. The consumption effect was defined as the economic activity generated from the personal spending of earned income. Total economic impact is the sum of direct effect, indirect effect, and consumption effect.

The direct effect was measured in terms of the value of crop production for 2003. Total economic impact was measured in four ways: gross output, value added, employment, and earned income. Each of these measures provides an alternative way of expressing total economic impact. Gross output is defined as businesses' sales or receipts plus inventory change. Value-added is defined as gross output minus intermediate inputs (goods and service inputs purchased from suppliers). It represents the value that is added by the application of capital, labor, and management to intermediate inputs in converting those inputs (e.g., fertilizer and fuel) to a finished product (e.g., corn for grain). Employment includes both full- and part-time workers. Earned income includes wages and salaries and proprietors' income. Earned income is less than total personal income, since it excludes dividends and interest income and transfer payments, such as Social Security payments.

The methodology for measuring the direct effect involved the identification of crops and the estimation of yields for irrigated and equivalent dryland crop production. Irrigated crops included corn for grain, soybeans, grain sorghum, winter wheat, dry edible beans, sugar beets, corn for silage, and alfalfa hay. The equivalent dryland crops included corn for grain, soybeans, grain sorghum, alfalfa hay, corn silage, winter wheat, sunflowers, and summer forage.

Scenario One: Normal Precipitation

Direct Economic Effect

Crop specific time-series regression equations were developed to estimate irrigated and equivalent dryland crop yields for assumed normal precipitation for 2003. Basically, the equations accounted for changes in technology (e.g., changes in farming practices) and annual precipitation.

Regression estimated crop yields for irrigated and equivalent dryland crops are given in column 2 of Tables 1 and 2. Column 3 of Tables 1 and 2 gives estimates of total crop production. Multiplying actual average price (column 4) times estimated production (column 3) determined the total value of production (column 5). The estimated total value of irrigated crop production was slightly more than \$3.1 billion (Table 1). A comparable estimate for equivalent dryland crop production was approximately \$1.9 billion (Table 2). The \$3.1 billion and \$1.9 billion are the direct effects of irrigated and equivalent dryland crop production, respectively, for the assumed normal precipitation for 2003. The difference of \$1.2 billion (\$3.1 billion - \$1.9 billion = \$1.2 billion) is the net direct economic effect of irrigation.

It should be noted that the total harvested acres for irrigated crops and equivalent dryland crops differs by 103,976 acres (column 1, Tables 1 and 2). The difference represents the estimate of the number of irrigated acres that would convert to summer fallow for equivalent dryland crop production.

Table 1
Irrigated Crops Output for Normal Weather Conditions: 2003

	Acres Harvested	Estimated Yield	Total Production	Ave. Price per Unit	Total Value of Production
Crop	1	2	3	4	5
Corn for Grain	4,765,000	185.5	883,907,500	\$2.39	\$2,112,538,925
Soybeans	1,940,000	53.5	103,790,000	\$7.02	\$728,605,800
Grain Sorghum	50,000	117	5,850,000	\$2.35	\$13,747,500
Winter Wheat	185,000	67	12,395,000	\$3.22	\$39,911,900
Dry Edible Beans	148,000	2.129	315,092	\$17.00	\$5,356,564
Alfalfa Hay	500,000	4.9	2,450,000	\$65.50	\$160,475,000
Corn Silage	115,000	19.6	2,254,000	\$23.90	\$53,870,600
Sugarbeets	42,400	20.3	860,720	\$42.30	\$36,408,456
Total	7,745,400				\$3,150,914,745

Total Economic Impact

As defined earlier, total economic impact is the sum of the direct effect, indirect effect, and consumption effect. Total impact can be calculated by determining industry multipliers from an input-output model of the state. These multipliers are numbers (greater than one) that when multiplied times an industry's direct effect, give an estimate of the total impact realized in the economy.

The economic impacts of irrigated and equivalent dryland crop production were estimated with industry multipliers developed from the IMPLAN PRITM (IMPLAN) software and associated data bases plus data collected from an irrigation survey. MIG, Inc. (Stillwater, MN) compiles economic data bases for U.S. counties and states using the North American Industry Classification System (NAICS). Data sources include the U.S. Department of Commerce, the U.S. Bureau of Labor Statistics, and other federal and state agencies.

MIG, Inc. does not disaggregate crop production between irrigated and dryland production. In order to incorporate crop irrigation into the state input-output model, a survey of crop irrigation expenses was conducted. A sample of 108 irrigators was drawn, and each irrigator was mailed a survey for 2003 irrigation expenses. The response rate of 36 percent was adequate to estimate 2003 crop irrigation expenses for Nebraska. These estimated production expenses were incorporated into the IMPLAN system, which then made it possible to calculate economic multipliers for both irrigated crop production and equivalent dryland crop production for 2003.

For assumed normal precipitation, estimated total value of irrigated crop production for 2003 (the direct effect) was slightly less than \$3.2 billion (\$3,150,914,745; Table 1). Using irrigation's economic multiplier of 2.46 from the state input-output model, the total economic impact of irrigation's \$3.15 output was estimated at \$7.76 billion (column 1, Table 3).

A similar total economic impact was calculated for the equivalent dryland crop output. The estimated total value for the equivalent dryland crop production for 2003 was \$1.9 billion (\$1,912,575,717; Table 2). Using dryland crop's economic multiplier of 2.15 from the state input-output model, total economic impact was estimated to be slightly more than \$4.1 billion (\$4,118,210,466; column 1, Table 3). Measured in terms of gross output, the net total economic impact of irrigation for 2003 was slightly more than \$3.6 billion (\$7,761,485,086 - \$4,118,210,466 = \$3,643,274,620) (column 1, Table 3).

The alternative measures of total economic impact, i.e., value added, employment, and earned income are given in columns 2, 3, and 4 of Table 3. Total economic impacts disaggregated on the basis of industry sectors are given in Panels A, B, and C of the Appendix.

The irrigation output multiplier of 2.46 calculated for this study is significantly higher than the estimated output multiplier 2.21 for the 1991 irrigation impact study based on 1985 data. The main reason for the difference was the increased use of professional services. Survey results for the current study indicated that irrigators devoted a higher proportion of total expenditures to professional services, such as accounting and management services. The output multiplier for equivalent dryland crop output increased from 2.07 (1991 study) to 2.15 (current study).

Table 3
Total Economic Impact for Normal Weather Conditions

	Gross Output 1	Value Added 2	Employ- ment 3	Earned Income 4
Irrigated Crops	\$7,761,485,086	\$3,887,133,694	78,457	\$2,438,004,651
Equivalent Dryland Crops	\$4,118,210,466	\$2,030,063,452	42,622	\$1,219,620,934
Difference	\$3,643,274,620	\$1,857,070,242	35,835	\$1,218,383,717

Scenario Two: Actual Precipitation

Direct Economic Effect

The actual annual precipitation in Nebraska for 2003 was a recorded 20.06 inches, making it the eighth lowest annual total for the 45-year period from 1960 through 2004. For 2002, the annual total was 15.92 inches making that total the second lowest for the 45-year period. The drought conditions that prevailed in 2002 substantially impacted the 2003 dryland crop output, because of very low subsoil moisture conditions for the 2003 planting season.

Tables 4 and 5 show the same irrigated and equivalent dryland crops, respectively, that were used for the impact estimates for assumed normal precipitation (Tables 1 and 2). The harvested acres (column 1 of Tables 4 and 5) also are identical to the acreages given in Tables 1 and 2. Column 2 of Tables 4 and 5 give crop yields. These estimates are state average yields for 2003. Crop prices given in column 4 of the tables are the same prices shown in column 4 of Tables 1 and 2. The estimated total value of irrigated crop production for 2003 was approximately \$3.15 billion (column 5, Table 4). The estimated total value of equivalent dryland crop production for 2003 was about \$1.49 billion (column 5, Table 5). The \$3.15 billion and the \$1.49 billion estimates are the direct effects for irrigated and equivalent dryland crop production for actual 2003 precipitation. The net direct effect of irrigation of \$1.6 billion (\$3.15 billion - \$1.49 billion = \$1.66 billion) is approximately \$400 million more than the net direct effect of irrigation for the assumed 2003 normal precipitation.

Table 4
Irrigated Crops for Actual Weather Conditions: 2003

Crop	Acres Harvested 1	Estimated Yield 2	Total Production 3	Ave. Price per Unit 4	Total Value of Production 5
Corn for Grain	4,765,000	186	883,907,500	\$2.39	\$2,112,538,925
Soybeans	1,940,000	54	103,790,000	\$7.02	\$728,605,800
Grain Sorghum	50,000	117	5,850,000	\$2.35	\$13,747,500
Winter Wheat	185,000	67	12,395,000	\$3.22	\$39,911,900
Dry Edible Beans	148,000	2	315,092	\$17.00	\$5,356,564
Alfalfa Hay	500,000	5	2,450,000	\$65.50	\$160,475,000
Corn Silage	115,000	19	2,208,000	\$23.90	\$52,771,200
Sugarbeets	42,400	20	860,720	\$42.30	\$36,408,456
Total	7,745,400				\$3,149,815,345

Source: Derived from data published by the U.S. Department of Agriculture.

Total Economic Impact

The gross output, value added, employment, and earned income measures of total economic impact for irrigated crops and equivalent dryland crops for actual 2003 precipitation are given in Table 6. Total economic impacts disaggregated on the basis of industry sectors are given in Panels D, E, and F of the Appendix.

The net total economic impact of irrigation for actual 2003 precipitation is substantially higher than that for assumed normal 2003 precipitation. The reason for the higher net total economic impact is irrigated crop yields are less affected by fluctuations in annual precipitation than are dryland crop yields. A comparison of irrigated and dryland yield variability is presented in the following section.

Table 6
Total Economic Impact for Actual Weather Conditions: 2003

	Gross Output	Value Added	Employment	Earned Income
Irrigated Crops	\$7,758,776,991	\$3,885,777,417	78,430	\$2,437,153,996
Equivalent Dryland Crops	\$3,230,042,682	\$1,592,242,953	33,430	\$956,587,261
Difference	\$4,528,734,309	\$2,293,534,464	45,000	\$1,480,566,735

Source: Derived from the Nebraska input-output model.

Irrigated and Dryland Crop Yield Variability

Crop yield variability was measured by calculating average deviations for both dryland and irrigated crop yields for the period 1982 through 2000. The 1982-2000 period was considered sufficient to give reasonably reliable estimates of crop yield variability plus the data represent a recent time period. Crop yield variability measures for the selected crops including corn for grain, soybeans, grain sorghum, winter wheat, corn for silage, and alfalfa hay are presented in Tables 12 through 17 of the Appendix. Table 12 of the Appendix is repeated below as Table 7 to illustrate how crop yield variability was measured.

Table 7 shows that during the period 1982 through 2000, dryland corn average yields varied from a high of 117.2 bushels in 1992 to a low of 58.4 bushels in 1983. Much of that variation was due to fluctuations in weather conditions. Irrigated corn average yields varied from a high of 161.3 bushels in 1998 to a low of 110.9 bushels in 1993.

Trend yield estimates (columns 2 and 5, Table 7) were used to measure the amount that actual yields varied from trend (or, average). Annual deviations (disregarding sign) were totaled and then divided by the total number of years to give an overall measure of variability. This overall measure of variability is called the average deviation. The average deviation for dryland corn was 13.4 bushels. The average deviation for irrigated corn was 8 bushels. For comparative purposes, average deviations were converted to percentages, called relative measures of average deviation. The relative average deviation for dryland corn was calculated by dividing the average deviation of 13.4 bushels by the median trend yield of 91.7 bushels; then, multiplying the result times 100. The relative average deviation for dryland corn yields was 14.6 percent, while the relative average deviation for irrigated corn was only 5.6 percent (Table 7). A comparison of crop yield variability for the selected irrigated and dryland crops

are given in Table 8. The yield data and calculations used in deriving the relative measures of variability (Table 8) are given in Tables 12 through 17 of the Appendix.

Reductions in yield variability through irrigation have resulted in providing the state's agribusiness processors a stable and reliable source of input. This means hundreds of millions of dollars in additional value added and earned income and thousands of additional jobs for Nebraska businesses and workers.

Table 7
Yield Variability of Corn for Grain: 1985-2000

<u>Dryland Corn Yields</u>				<u>Irrigated Corn Yields</u>			
Year	Actual Yield	Baseline Yield	Deviation from Baseline	Year	Actual Yield	Baseline Yield	Deviation from Baseline
	1	2	3		4	5	6
1982	84.6	77.7	6.9	1982	123	129.2	-6.2
1983	58.4	79.3	-20.9	1983	116	130.7	-14.7

Total Economic Impact of New Farm Machinery and Other New Equipment Purchases

The irrigation survey for 2003 irrigated crop expenditures included a section on purchases of new farm machinery and equipment for 2003. The survey results on capital expenditures were extrapolated to a state estimate of \$444.4 million for new farm machinery and equipment purchases during 2003. Examples of farm equipment include irrigation pumps and motors, irrigation pipe, and hand held power tools. Examples of farm machinery include combines, corn planters, and tractors. Added to the \$444.4 million was \$981,000 for computer equipment (Table 9) for an estimated total expenditure of \$445,434,685. The \$981,000 was reported in the *2002 Census of Agriculture for Nebraska*, and it was assumed that 2003 computer expenditures remained at the 2002 level.

Table 9
New Farm Machinery and Other New Equipment Purchases
By Irrigators: 2003

Type of Purchase	Estimated Total Value of Purchases
New Farm Machinery	\$278,506,662
Other New Equipment	\$165,947,023
Computer & Related Items	\$981,000

Source: Derived from survey data and published data from the U.S. Department of Agriculture.

Some of the new machinery and equipment purchases were made directly from manufacturers that included manufacturers located outside Nebraska. Other purchases were made through wholesalers, retailers, or both. Assumptions were used to separate in-state suppliers from out-of-state suppliers (Table 10). These assumptions were necessary to calculate the total economic impact associated with purchases from in-state suppliers.

A state input-output model was used to calculate total economic impact for Nebraska. Total economic impact was measured in terms of gross output, value added, employment, and earned income (Table 11). Total economic impacts disaggregated on the basis of industry sectors are presented in Table 18 of the Appendix.

Table 10
Manufacturer and Distribution Location Assumptions: 2003

	Manufacturing		Distribution (100% in-state)	
	In-state	Out-of- State	Wholesale	Retail
Implements	20%	80%	100%	0%
Equipment	80%	20%	75%	25%
Computer Hardware	5%	95%	0%	100%

Source: Assumptions

The total economic impact of \$293 million (gross output) is slightly less than two-thirds of the direct expenditures of \$445.4 million (Table 9). This result shows that a very large portion of the \$445.4 million involved out-of-state manufacturers. Payments to out-of-state manufacturers represent transaction leakages from the state's economy.

Table 11
Total Economic Impact of Capital Expenditures: 2003

Impact Measure	Impact
Gross Output	\$293,043,049
Value Added	\$167,260,011
Employment	3,289
Earned Income	\$154,636,684

Table 18
Economic Impact of Capital Purchases, 2003

Total Gross Output Impact by Industry Sector	
Crop Production	\$1,103,183
Livestock & Livestock Products	\$1,934,539
Agriculture Processing	\$11,517,004
Other Manufacturing	\$14,164,054
Wholesale and Retail Trade	\$118,598,092
Transportation and Communications	\$20,318,423
Utilities	\$8,817,101
F.I.R.E., Leasing and Rentals	\$40,021,237
Services and Education	\$75,539,680
Other	\$1,029,736
Total Gross Output	\$293,043,049

Total Value Added Impact by Industry Sector	
Crop Production	\$549,139
Livestock & Livestock Products	\$192,187
Agriculture Processing	\$2,791,743
Other Manufacturing	\$4,337,916
Wholesale and Retail Trade	\$86,405,971
Transportation and Communications	\$0
Utilities	\$6,476,394
F.I.R.E., Leasing and Rentals	\$21,779,813
Services and Education	\$43,685,293
Other	\$1,041,556
Total Value Added	\$167,260,011

Total Employment Impact by Industry Sector	
Crop Production	6
Livestock & Livestock Products	10
Agriculture Processing	38
Other Manufacturing	61
Wholesale and Retail Trade	1,413
Transportation and Communications	139
Utilities	12
F.I.R.E., Leasing and Rentals	285
Services and Education	1,304
Other	22
Total Employment Impact	3,289
